Brief Summary: Object-Oriented Programming in Python

Overview of classes, magic methods, and file structure

We covered core concepts in object-oriented programming in Python, focusing on classes, objects, and magic methods such as __init__, __repr__, __str__, and __call__. You learned how to use self, define default parameter values, and verify that random dice rolls (such as a d20) stay within valid boundaries.

We also looked at how to organize code into separate modules like character.py and items.py to avoid ImportError and circular dependencies. Finally, we explored optional parameters (such as weapon=None), how the attack method handles both unarmed combat and dynamic dice rolls, and how to ensure damage is recalculated on every attack rather than remaining static.
